Chapter 1: Basic Elements of C++

Objectives

In this chapter, you will:

- Become familiar with the basic components of a C++ program, including functions, special symbols, and identifiers
- Explore simple data types
- Discover how to use arithmetic operators
- Examine how a program evaluates arithmetic expressions

Objectives (continued)

- Learn what an assignment statement is and what it does
- Become familiar with the string data type
- Discover how to input data into memory using input statements
- Become familiar with the use of increment and decrement operators
- Examine ways to output results using output statements

Objectives (continued)

- Learn how to use preprocessor directives and why they are necessary
- Explore how to properly structure a program, including using comments to document a program
- Learn how to write a C++ program

The Basics of a C++ Program

 <u>Function</u>: collection of statements; when executed, accomplishes something

- May be predefined or standard

- <u>Syntax</u>: rules that specify which statements (instructions) are legal
- <u>Programming language</u>: a set of rules, symbols, and special words
- <u>Semantic rule</u>: meaning of the instruction

Comments

- Comments are for the reader, not the compiler
- Two types:

- Single line

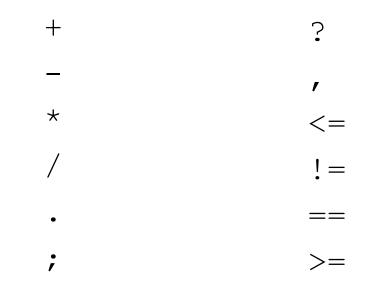

// This is a C++ program. It prints the sentence:
// Welcome to C++ Programming.

- Multiple line

```
/*
  You can include comments that can
  occupy several lines.
*/
```

Special Symbols

• Special symbols

Reserved Words (Keywords)

- Reserved words, keywords, or word symbols
 Include:
 - int
 - float
 - double
 - char
 - const
 - void
 - return

Identifiers

- Consist of letters, digits, and the underscore character (_)
- Must begin with a letter or underscore
- C++ is case sensitive
 - NUMBER is not the same as number
- Two predefined identifiers are cout and cin
- Unlike reserved words, predefined identifiers may be redefined, but it is not a good idea

Identifiers (continued)

- The following are legal identifiers in C++:
 - first
 - conversion
 - payRate

TABLE 2-1 Examples of Illegal Identifiers

| Illegal Identifier | Description | |
|--------------------|---|--|
| employee Salary | There can be no space between employee and Salary. | |
| Hello! | The exclamation mark cannot be used in an identifier. | |
| one+two | The symbol + cannot be used in an identifier. | |
| 2nd | An identifier cannot begin with a digit. | |

Whitespaces

- Every C++ program contains whitespaces
 Include blanks, tabs, and newline characters
- Used to separate special symbols, reserved words, and identifiers
- Proper utilization of whitespaces is important
 - Can be used to make the program readable

Data Types

- Data type: set of values together with a set of operations
- C++ data types fall into three categories:

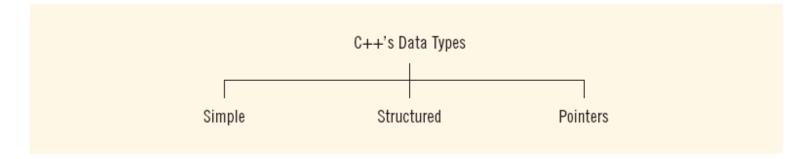

FIGURE 2-1 C++ data types

Simple Data Types

- Three categories of simple data
 - Integral: integers (numbers without a decimal)
 - Floating-point: decimal numbers
 - Enumeration type: user-defined data type

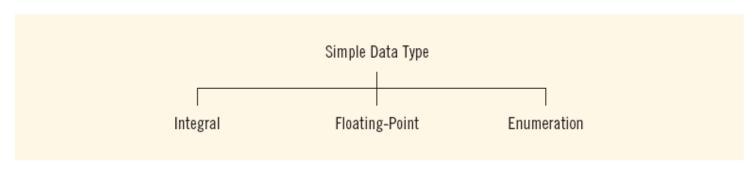

FIGURE 2-2 Simple data types

Simple Data Types (continued)

 Integral data types are further classified into nine categories:

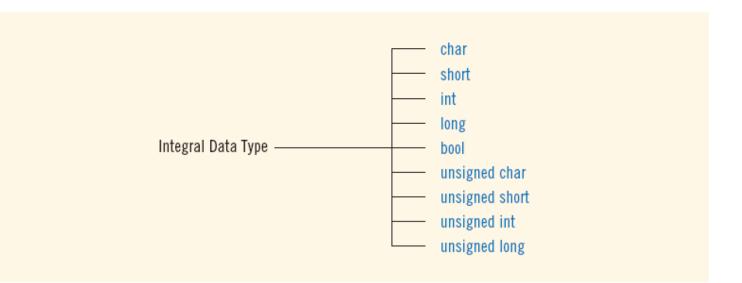

FIGURE 2-3 Integral data types

Simple Data Types (continued)

TABLE 2-2 Values and Memory Allocation for Three Simple Data Types

| Data Type | Values | Storage (in bytes) |
|-----------|---------------------------|--------------------|
| int | -2147483648 to 2147483647 | 4 |
| bool | true and false | 1 |
| char | -128 to 127 | 1 |

 Different compilers may allow different ranges of values

int Data Type

- Examples:
 - -6728
 - 0
 - 78
 - +763
- Positive integers do not need a + sign
- No commas are used within an integer
 - Commas are used for separating items in a list

bool Data Type

- bool type
 - Two values: true and false
 - Manipulate logical (Boolean) expressions
- true and false are called logical values
- bool, true, and false are reserved words

char Data Type

- The smallest integral data type
- Used for <u>characters</u>: letters, digits, and special symbols
- Each character is enclosed in single quotes

- 'A', 'a', '0', '*', '+', '\$', '&'

 A blank space is a character and is written ' ', with a space left between the single quotes

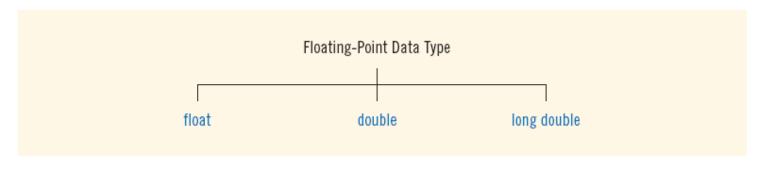

Floating-Point Data Types

 C++ uses scientific notation to represent real numbers (floating-point notation)

| TABLE 2-3 | Examples of Real | Numbers | Printed in C++ | Floating-Point I | Notation |
|-----------|------------------|---------|----------------|------------------|----------|
|-----------|------------------|---------|----------------|------------------|----------|

| Real Number | C++ Floating-Point Notation |
|-------------|-----------------------------|
| 75.924 | 7.592400E1 |
| 0.18 | 1.80000E-1 |
| 0.0000453 | 4.530000E-5 |
| -1.482 | -1.482000E0 |
| 7800.0 | 7.80000E3 |

Floating-Point Data Types (continued)

- float: represents any real number
 - Range: -3.4E+38 to 3.4E+38 (four bytes)
- double: represents any real number
 - Range: -1.7E+308 to 1.7E+308 (eight bytes)
- On most newer compilers, data types double and long double are same

Floating-Point Data Types (continued)

- Maximum number of significant digits (decimal places) for float values is 6 or 7
- Maximum number of significant digits for double is 15
- <u>Precision</u>: maximum number of significant digits
 - Float values are called single precision
 - Double values are called double precision

Arithmetic Operators and Operator Precedence

- C++ arithmetic operators:
 - + addition
 - subtraction
 - * multiplication
 - / division
 - % modulus operator
- +, -, *, and / can be used with integral and floating-point data types
- Operators can be unary or binary

Order of Precedence

- All operations inside of () are evaluated first
- *, /, and % are at the same level of precedence and are evaluated next
- + and have the same level of precedence and are evaluated last
- When operators are on the same level
 Performed from left to right (associativity)
- 3 * 7 6 + 2 * 5 / 4 + 6 means
 (((3 * 7) 6) + ((2 * 5) / 4)) + 6

Expressions

- If all operands are integers
 - Expression is called an integral expression
 - Yields an integral result
 - Example: 2 + 3 * 5
- If all operands are floating-point
 - Expression is called a floating-point expression
 - Yields a floating-point result
 - Example: 12.8 * 17.5 34.50

Mixed Expressions

- Mixed expression:
 - Has operands of different data types
 - Contains integers and floating-point
- Examples of mixed expressions:

- 6 / 4 + 3.9
- 5.4 * 2 13.6 + 18 / 2

Mixed Expressions (continued)

- Evaluation rules:
 - If operator has same types of operands
 - Evaluated according to the type of the operands
 - If operator has both types of operands
 - Integer is changed to floating-point
 - Operator is evaluated
 - Result is floating-point
 - Entire expression is evaluated according to precedence rules

Type Conversion (Casting)

- <u>Implicit type coercion</u>: when value of one type is automatically changed to another type
- <u>Cast operator</u>: provides explicit type conversion

static_cast<dataTypeName>(expression)

Type Conversion (continued)

EXAMPLE 2-9

Expression

```
static_cast<int>(7.9)
static_cast<int>(3.3)
static_cast<double>(25)
static_cast<double>(5+3)
static_cast<double>(15) / 2
```

```
static_cast<double>(15/2)
```

```
static_cast<int>(7.8 +
static_cast<double>(15) / 2)
```

```
static_cast<int>(7.8 +
static_cast<double>(15/2))
```

Evaluates to

```
7
3
25.0
= static_cast<double>(8) = 8.0
= 15.0 / 2
(because static_cast<double>(15) = 15.0)
= 15.0 / 2.0 = 7.5
= static_cast<double>(7) (because 15 / 2 = 7)
= 7.0
= static_cast<int>(7.8 + 7.5)
= static_cast<int>(15.3)
= 15
= static_cast<int>(7.8 + 7.0)
= static_cast<int>(14.8)
= 14
```

string Type

- Programmer-defined type supplied in ANSI/ISO Standard C++ library
- Sequence of zero or more characters
- Enclosed in double quotation marks
- Null: a string with no characters
- Each character has relative position in string
 - Position of first character is 0
- Length of a string is number of characters in it
 Example: length of "William Jacob" is 13

Input

- Data must be loaded into main memory before it can be manipulated
- Storing data in memory is a two-step process:
 - Instruct computer to allocate memory
 - Include statements to put data into memory

Allocating Memory with Constants and Variables

- <u>Named constant</u>: memory location whose content can't change during execution
- The syntax to declare a named constant is:

const dataType identifier = value;

• In C++, const is a reserved word

EXAMPLE 2-11

Consider the following C++ statements:

```
const double CONVERSION = 2.54;
const int NO_OF_STUDENTS = 20;
const char BLANK = ' ';
const double PAY RATE = 15.75;
```

C++ Programming: From Problem Analysis to Program Design, Fourth Edition

Allocating Memory with Constants and Variables (continued)

- <u>Variable</u>: memory location whose content may change during execution
- The syntax to declare a named constant is:

```
dataType identifier, identifier, . . .;
```

EXAMPLE 2-12

Consider the following statements:

```
double amountDue;
int counter;
char ch;
int x, y;
string name;
```

Putting Data into Variables

- Ways to place data into a variable:
 - Use C++'s assignment statement
 - Use input (read) statements

Assignment Statement

• The assignment statement takes the form:

variable = expression;

- Expression is evaluated and its value is assigned to the variable on the left side
- In C++, = is called the assignment operator

Assignment Statement (continued)

EXAMPLE 2-13

```
int num1, num2;
double sale;
char first;
string str;
num1 = 4;
num2 = 4 * 5 - 11;
sale = 0.02 * 1000;
first = 'D';
str = "It is a sunny day.";
```

EXAMPLE 2-14

- 1. num1 = 18;
- 2. num1 = num1 + 27;
- 3. num2 = num1;
- 4. num3 = num2 / 5;
- 5. num3 = num3 / 4;

C++ Programming: From Problem Analysis to Program Design, Fourth Edition

Saving and Using the Value of an Expression

- To save the value of an expression:
 - Declare a variable of the appropriate data type
 - Assign the value of the expression to the variable that was declared
 - Use the assignment statement
- Wherever the value of the expression is needed, use the variable holding the value

Declaring & Initializing Variables

- Variables can be initialized when declared: int first=13, second=10; char ch=' '; double x=12.6;
- All variables must be initialized before they are used
 - But not necessarily during declaration

Input (Read) Statement

• cin is used with >> to gather input

cin >> variable >> variable ...;

- The stream extraction operator is >>
- For example, if miles is a double variable cin >> miles;
 - Causes computer to get a value of type double
 - Places it in the variable miles

Input (Read) Statement (continued)

- Using more than one variable in cin allows more than one value to be read at a time
- For example, if feet and inches are variables of type int, a statement such as:
 cin >> feet >> inches;
 - Inputs two integers from the keyboard
 - Places them in variables feet and inches respectively

Input (Read) Statement (continued)

EXAMPLE 2-17

```
#include <iostream>
using namespace std;
int main()
ł
    int feet;
    int inches;
    cout << "Enter two integers separated by spaces: ";
    cin >> feet >> inches;
    cout << endl;
    cout << "Feet = " << feet << endl;</pre>
    cout << "Inches = " << inches << endl;
    return 0;
Sample Run: (In this sample run, the user input is shaded.)
Enter two integers separated by spaces: 23 7
Feet = 23
Inches = 7
```

C++ Programming: From Problem Analysis to Program Design, Fourth Edition

Variable Initialization

- There are two ways to initialize a variable: int feet;
 - By using the assignment statement
 feet = 35;
 - By using a read statement
 cin >> feet;

Increment & Decrement Operators

- Increment operator: increment variable by 1
 - **Pre-increment:** ++variable
 - Post-increment: variable++
- Decrement operator: decrement variable by 1
 - **Pre-decrement:** --variable
 - Post-decrement: variable-
- What is the difference between the following?

$$\begin{array}{cccc} x &=& 5; \\ y &=& ++x; \end{array} & \begin{array}{cccc} x &=& 5; \\ y &=& x++; \end{array} \\ \end{array}$$

• The syntax of cout and << is:

cout << expression or manipulator << expression or manipulator...;</pre>

- Called an output statement

- The stream insertion operator is <<
- Expression evaluated and its value is printed at the current cursor position on the screen

Output (continued)

- A manipulator is used to format the output
 - Example: endl causes insertion point to move to beginning of next line

EXAMPLE 2-21

| | Statement | | Output |
|---|-----------|------------------------------|--------------|
| 1 | cout << | 29 / 4 << endl; | 7 |
| 2 | cout << | "Hello there." << endl; | Hello there. |
| 3 | cout << | 12 << endl; | 12 |
| 4 | cout << | "4 + 7" << endl; | 4 + 7 |
| 5 | cout << | 4 + 7 << endl; | 11 |
| 6 | cout << | 'A' << endl; | A |
| 7 | cout << | "4 + 7 = " << 4 + 7 << endl; | 4 + 7 = 11 |
| 8 | cout << | 2 + 3 * 5 << endl; | 17 |
| 9 | cout << | "Hello \nthere." << endl; | Hello |
| | | | there. |

C++ Programming: From Problem Analysis to Program Design, Fourth Edition

Output (continued)

- The new line character is '\n'
 - May appear anywhere in the string

```
cout << "Hello there.";</pre>
```

```
cout << "My name is James.";</pre>
```

• Output:

Hello there.My name is James.

cout << "Hello there.\n"; cout << "My name is James."; • Output:

```
Hello there.
```

```
My name is James.
```

Output (continued)

TABLE 2-4 Commonly Used Escape Sequences

| | Escape Sequence | Description |
|------------|--------------------|---|
| \ n | Newline | Cursor moves to the beginning of the next line |
| \t | Tab | Cursor moves to the next tab stop |
| \b | Backspace | Cursor moves one space to the left |
| \r | Return | Cursor moves to the beginning of the current line (not the next line) |
| 11 | Backslash | Backslash is printed |
| \' | Single quotation | Single quotation mark is printed |
| \ " | Double quotation | Double quotation mark is printed |

Preprocessor Directives

- C++ has a small number of operations
- Many functions and symbols needed to run a C++ program are provided as collection of libraries
- Every library has a name and is referred to by a header file
- Preprocessor directives are commands supplied to the preprocessor
- All preprocessor commands begin with #
- No semicolon at the end of these commands

Preprocessor Directives (continued)

• Syntax to include a header file:

#include <headerFileName>

• For example:

#include <iostream>

- Causes the preprocessor to include the header file iostream in the program

namespace and Using cin and cout in a Program

- cin and cout are declared in the header file iostream, but within std namespace
- To use cin and cout in a program, use the following two statements:

#include <iostream>

using namespace std;

Using the string Data Type in a Program

- To use the string type, you need to access its definition from the header file string
- Include the following preprocessor directive: #include <string>

Creating a C++ Program

- C++ program has two parts:
 - Preprocessor directives
 - The program
- Preprocessor directives and program statements constitute C++ source code (.cpp)
- Compiler generates object code (.obj)
- Executable code is produced and saved in a file with the file extension .exe

Creating a C++ Program (continued)

- A C++ program is a collection of functions, one of which is the function main
- The first line of the function main is called the heading of the function:

int main()

- The statements enclosed between the curly braces ({ and }) form the body of the function
 - Contains two types of statements:
 - Declaration statements
 - Executable statements

EXAMPLE 2-29

```
#include <iostream>
                                                       //Line 1
                                                       //Line 2
using namespace std;
                                                       //Line 3
const int NUMBER = 12;
                                                       //Line 4
int main()
                                                       //Line 5
                                                       //Line 6
    int firstNum;
    int secondNum;
                                                       //Line 7
                                                       //Line 8
    firstNum = 18;
    cout << "Line 9: firstNum = " << firstNum
         << endl;
                                                       //Line 9
                                                       //Line 10
    cout << "Line 10: Enter an integer: ";</pre>
                                                       //Line 11
    cin >> secondNum;
                                                       //Line 12
    cout << endl;
    cout << "Line 13: secondNum = " << secondNum
         << endl;
                                                       //Line 13
    firstNum = firstNum + NUMBER + 2 * secondNum;
                                                      //Line 14
    cout << "Line 15: The new value of "
         << "firstNum = " << firstNum << endl;
                                                      //Line 15
   return 0;
                                                       //Line 16
                                                       //Line 17
}
```

Creating a C++ Program (continued)

Sample Run:

Line 9: firstNum = 18

Line 10: Enter an integer: 15

```
Line 13: secondNum = 15
Line 15: The new value of firstNum = 60
```

Program Style and Form

- Every C++ program has a function main
- It must also follow the syntax rules
- Other rules serve the purpose of giving precise meaning to the language

Errors in syntax are found in compilation
 int x; //Line 1
 int y //Line 2: error
 double z; //Line 3

y = w + x; //Line 4: error

Use of Blanks

- In C++, you use one or more blanks to separate numbers when data is input
- Used to separate reserved words and identifiers from each other and from other symbols
- Must never appear within a reserved word or identifier

Use of Semicolons, Brackets, and Commas

- All C++ statements end with a semicolon
 Also called a statement terminator
- { and } are not C++ statements
- Commas separate items in a list

Semantics

- Possible to remove all syntax errors in a program and still not have it run
- Even if it runs, it may still not do what you meant it to do
- For example,

2 + 3 * 5 and (2 + 3) * 5

are both syntactically correct expressions, but have different meanings

Naming Identifiers

- Identifiers can be self-documenting:
 - CENTIMETERS_PER_INCH
- Avoid run-together words :
 - annualsale
 - Solution:
 - Capitalize the beginning of each new word
 - annualSale
 - Inserting an underscore just before a new word
 - annual_sale

Prompt Lines

<u>Prompt lines</u>: executable statements that inform the user what to do

Documentation

- A well-documented program is easier to understand and modify
- You use comments to document programs
- Comments should appear in a program to:
 - Explain the purpose of the program
 - Identify who wrote it
 - Explain the purpose of particular statements

Form and Style

- Consider two ways of declaring variables:
 - Method 1

int feet, inch;

double x, y;

- Method 2

int a,b;double x,y;

 Both are correct; however, the second is hard to read

More on Assignment Statements

 C++ has special assignment statements called compound assignments

+=, -=, *=, /=, and %=

• Example:

Programming Example: Convert Length

- Write a program that takes as input a given length expressed in feet and inches
 - Convert and output the length in centimeters
- Input: length in feet and inches
- <u>Output</u>: equivalent length in centimeters
- Lengths are given in feet and inches
- Program computes the equivalent length in centimeters
- One inch is equal to 2.54 centimeters

Programming Example: Convert Length (continued)

- Convert the length in feet and inches to all inches:
 - Multiply the number of feet by 12
 - Add given inches
- Use the conversion formula (1 inch = 2.54 centimeters) to find the equivalent length in centimeters

Programming Example: Convert Length (continued)

- The algorithm is as follows:
 - Get the length in feet and inches
 - Convert the length into total inches
 - Convert total inches into centimeters
 - Output centimeters

Programming Example: Variables and Constants

• Variables

int feet; //variable to hold given feet int inches; //variable to hold given inches int totalInches; //variable to hold total inches double centimeters; //variable to hold length in //centimeters

Named Constant

const double CENTIMETERS_PER_INCH = 2.54; const int INCHES_PER_FOOT = 12;

Programming Example: Main Algorithm

- Prompt user for input
- Get data
- Echo the input (output the input)
- Find length in inches
- Output length in inches
- Convert length to centimeters
- Output length in centimeters

Programming Example: Putting It Together

- Program begins with comments
- System resources will be used for I/O
- Use input statements to get data and output statements to print results
- Data comes from keyboard and the output will display on the screen
- The first statement of the program, after comments, is preprocessor directive to include header file iostream

Programming Example: Putting It Together (continued)

- Two types of memory locations for data manipulation:
 - Named constants
 - Usually put before main
 - Variables
- This program has only one function (main), which will contain all the code
- The program needs variables to manipulate data, which are declared in main

Programming Example: Body of the Function

The body of the function main has the following form:
 int main ()

```
declare variables
statements
return 0;
```

Programming Example: Writing a Complete Program

- Begin the program with comments for documentation
- Include header files
- Declare named constants, if any
- Write the definition of the function main

```
using namespace std;
```

```
//Named constants
const double CENTIMETERS PER INCH = 2.54;
const int INCHES PER FOOT = 12;
int main ()
        //Declare variables
   int feet, inches;
   int totalInches;
   double centimeter;
        //Statements: Step 1 - Step 7
   cout << "Enter two integers, one for feet and "
        << "one for inches: ";
                                                      //Step 1
    cin >> feet >> inches;
                                                      //Step 2
    cout << endl;
    cout << "The numbers you entered are " << feet
         << " for feet and " << inches
         << " for inches. " << endl;
                                                       //Step 3
    totalInches = INCHES PER FOOT * feet + inches;
                                                      //Step 4
    cout << "The total number of inches = "
         << totalInches << endl;
                                                       //Step 5
    centimeter = CENTIMETERS PER INCH * totalInches; //Step 6
    cout << "The number of centimeters = "
         << centimeter << endl;
                                                       //Step 7
    return 0;
```

C++ Programming: From Problem Analysis to Program Design, Fourth Edition

Programming Example: Sample Run

Enter two integers, one for feet, one for inches: 15 7

The numbers you entered are 15 for feet and 7 for inches. The total number of inches = 187The number of centimeters = 474.98

Summary

- <u>C++ program</u>: collection of functions where each program has a function called main
- Identifier consists of letters, digits, and underscores, and begins with letter or underscore
- The arithmetic operators in C++ are addition (+), subtraction (-),multiplication (*), division (/), and modulus (%)
- Arithmetic expressions are evaluated using the precedence associativity rules

Summary (continued)

- All operands in an integral expression are integers and all operands in a floating-point expression are decimal numbers
- <u>Mixed expression</u>: contains both integers and decimal numbers
- Use the cast operator to explicitly convert values from one data type to another
- A named constant is initialized when declared
- All variables must be declared before used

Summary (continued)

- Use cin and stream extraction operator >> to input from the standard input device
- Use cout and stream insertion operator << to output to the standard output device
- Preprocessor commands are processed before the program goes through the compiler
- A file containing a C++ program usually ends with the extension .cpp
